# Moving-head Disk Mechanism

# Elements of File Management

# Disk Scheduling

- The operating system is responsible for using hardware efficiently — for the disk drives, this means having a fast access time and disk bandwidth.
- Access time has two major components:
  - Seek time is the time for the disk are to move the heads to the cylinder containing the desired sector.
  - Rotational latency is the additional time waiting for the disk to rotate the desired sector to the disk head.
- Minimize seek time  $\approx$  seek distance.
- Disk bandwidth is the total number of bytes transferred, divided by the total time between the first request for service and the completion of last transfer.

# Components of Disk I/O Transfer

## Disk Structure

- Disk drives are addressed as large 1-dimensional arrays of logical blocks, where the logical block is the smallest unit of transfer.
- The 1-dimensional array of logical blocks is mapped into the sectors of the disk sequentially:
  - Sector 0 is the first sector of the first track on the outermost cylinder.
  - Mapping proceeds in order through that track, then the rest of the tracks in that cylinder, and then through the rest of the cylinders from outermost to innermost.

## Disk Scheduling Algorithms

- Several algorithms exist to schedule the servicing of disk I/O requests.
- We illustrate them with a I/O request queue (cylinders are between 0-199):

queue = 98, 183, 37, 122, 14, 124, 65, 67

head starts at 53

# First Come First Serve (FCFS) Example

queue = 98, 183, 37, 122, 14, 124, 65, 67

head starts at 53

Illustration shows total head movement of 640 cylinders.

## First Come First Serve (FCFS)

- Handle I/O requests sequentially.
- Fair to all processes.
- Approaches random scheduling in performance if there are many processes/requests.
- Suffers from global zigzag effect.

## Shortest Seek Time First (SSTF) Example

queue = 98, 183, 37, 122, 14, 124, 65, 67

head starts at 53

Illustration shows total head movement of 236 cylinders.

## Shortest Seek Time First (SSTF)

- Selects the request with the minimum seek time from the current head position.
- Also called Shortest Seek Distance First (SSDF) – It's easier to compute distances.
- It's biased in favor of the middle cylinders requests.
- SSTF scheduling is a form of SJF scheduling; may cause starvation of some requests.

# Elevator Algorithms

- Algorithms based on the common elevator principle.
- Four combinations of Elevator algorithms:
  - Service in both directions or in only one direction.
  - Go until last cylinder or until last I/O request.

Go until Direction	Go until the last cylinder	Go until the last request
Service both directions	 <b>Scan</b>	<b>Look</b>
Service in only one direction	<b>C-Scan</b>	<b>C-Look</b>

# Scan Example

queue = 98, 183, 37, 122, 14, 124, 65, 67

head starts at 53

Illustration shows total head movement of 208 cylinders.

## Scan

- The disk arm starts at one end of the disk, and moves toward the other end, servicing requests until it gets to the other end of the disk, where the head movement is reversed and servicing continues.
- It moves in both directions until both ends.
- Tends to stay more at the ends so more fair to the extreme cylinder requests.

# C-Scan Example

queue = 98, 183, 37, 122, 14, 124, 65, 67

head starts at 53

## Look

- The disk arm starts at the first I/O request on the disk, and moves toward the last I/O request on the other end, servicing requests until it gets to the other extreme I/O request on the disk, where the head movement is reversed and servicing continues.
- It moves in both directions until both last I/O requests; more inclined to serve the middle cylinder requests.

# C-Look Example

queue 98, 183, 37, 122, 14, 124, 65, 67

head starts at 53

## C-Look

- Look version of C-Scan.
- Arm only goes as far as the last request in each direction, then reverses direction immediately, without first going all the way to the end of the disk.
- In general, Circular versions are more fair but pay with a larger total seek time.
- Scan versions have a larger total seek time than the corresponding Look versions.

## Other Disk Scheduling Policies

- Pickup
  - A combination of FCFS and Look.
  - Goes to next I/O request by FCFS but services all existing requests on the way to it.
- Priority
  - Goal is not to optimize disk use but to meet other objectives.
  - Short batch jobs may have higher priority.
  - Provide good interactive response time.

## Scan Algorithm Variations

- FScan
  - Use two queues.
  - One queue is empty to receive new requests.
- N-step-Scan
  - Segments the disk request queue into subqueues of length  $N$ .
  - Subqueues are processed one at a time, using Scan.
  - New requests added to other queue when a certain queue is processed.

## Selecting a Disk-Scheduling Algorithm

- Performance depends on the number and types of requests.
- Requests for disk service can be influenced by the file-allocation method.
- The disk-scheduling algorithm should be written as a separate module of the operating system, allowing it to be replaced with a different algorithm if necessary.
